Introduction

If things don't go your way in predictive modeling, use XGboost. XGBoost algorithm has become the ultimate weapon of many data scientist. It's a highly sophisticated algorithm, powerful enough to deal with all sorts of irregularities of data.

Building a model using XGBoost is easy. But, improving the model using XGBoost is difficult (at least I struggled a lot). This algorithm uses multiple parameters. To improve the model, parameter tuning is

Contact Number:

1. Regularization:

LEARN → ENGAGE COMPETE GET HIRED COURSES
Standard GBM implementation has no regularization
(<https://www.analyticsvidhya.com/blog/2015/02/avoid-overfitting-regularization-like-xgboost/>)

CONTACT OVERFITTING REGULARIZATION LIKE XGBOOST THEREFORE IT ALSO HELPS TO REDUCE OVERRFITTING.

- In fact, XGBoost is also known as '**regularized boosting**' technique.

2. Parallel Processing:

- XGBoost implements parallel processing and is **blazingly faster** as compared to GBM.
- But hang on, we know that boosting (<https://www.analyticsvidhya.com/blog/2015/11/quick-introduction-boosting-algorithms-machine-learning/>) is sequential process so how can it be parallelized? We know that each tree can be built only after the previous one, so what stops us from making a tree using all cores? I hope you get where I'm coming from. Check this link (<http://zhanpengfang.github.io/418home.html>). out to explore further.
- XGBoost also supports implementation on Hadoop.

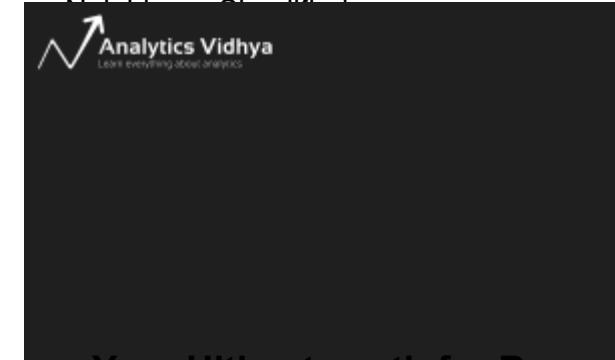

3. High Flexibility

- XGBoost allow users to define **custom optimization objectives and evaluation criteria**.
- This adds a whole new dimension to the model and there is no limit to what we can do.

4. Handling Missing Values

(<https://www.analyticsvidhya.com/contests/practice-series/intel-scene-classification-challenge/>?utm_source=AVStickyBanner2&utm_medium=display2&uti

Introduction to k-Nearest

science journey
[DataHack Radio #17:
X1AnalyticsVidhya+DS101+2018T2/about?](https://farmings.analyticsvidhya.com/courses/course-X1AnalyticsVidhya+DS101+2018T2/about?)

- XGBoost has an in-built routine to handle missing values.
- LEARN** ○ User is required to supply a different value than other observations and pass that as a parameter. XGBoost tries to learn different things as it encounters a missing value on each node and learns which path to take for missing values in future.
- CONTACT** (<https://www.analyticsvidhya.com/contact>)

5. Tree Pruning:

- A GBM would stop splitting a node when it encounters a negative loss in the split. Thus it is more of a **greedy algorithm**.
- XGBoost on the other hand make **splits upto the max_depth** specified and then start **pruning** the tree backwards and remove splits beyond which there is no positive gain.
- Another advantage is that sometimes a split of negative loss say -2 may be followed by a split of positive loss +10. GBM would stop as it encounters -2. But XGBoost will go deeper and it will see a combined effect of +8 of the split and keep both.

6. Built-in Cross-Validation

- XGBoost allows user to run a **cross-validation at each iteration** of the boosting process and thus it is easy to get the exact optimum number of boosting iterations in a single run.
- This is unlike GBM where we have to run a grid-search and only a limited values can be tested.

7. Continue on Existing Model

- LEARN → ENGAGE → COMPETE → GET HIRED → COURSES
User can start training an XGBoost model from its last iteration of previous run. This can be of significant advantage in certain specific applications.
- CONTACT (<https://www.analyticsvidhya.com/contact/>)
- GBM implementation of sklearn also has this feature so they are even on this point.

I hope now you understand the sheer power XGBoost algorithm. Note that these are the points which I could muster. You know a few more? Feel free to drop a comment below and I will update the list.

Did I whet your appetite ? Good. You can refer to following web-pages for a deeper understanding:

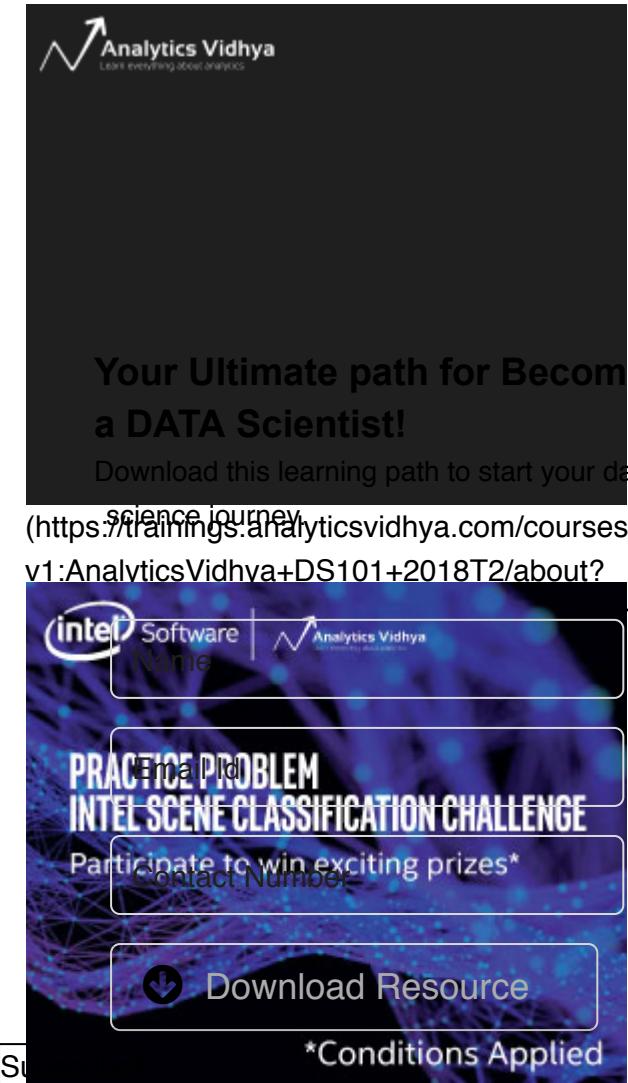

- XGBoost Guide – Introduction to Boosted Trees (<http://xgboost.readthedocs.org/en/latest/model.html>).
- Words from the Author of XGBoost (<https://www.youtube.com/watch?v=X47SGnTMZIU>) [Video]

2. XGBoost Parameters

The overall parameters have been divided into 3 categories by XGBoost authors:

1. **General Parameters:** Guide the overall functioning
2. **Booster Parameters:** Guide the individual booster (tree/regression) at each step

https://datahack.analyticsvidhya.com/contest/practice-problem-intel-scene-classification-challenge/?utm_source=AVStickyBanner2&utm_medium=display2&uti

3. Learning Task Parameters: Guide the optimization performed
LEARN ▾ ENGAGE ▾ COMPETE ▾ GET HIRED ▾ COURSES ▾

I will give analogies to GBM here and highly recommend to read [this article](https://www.analyticsvidhya.com/blog/2016/02/complete-guide-parameter-tuning-gradient-boosting-gbm-python/) (<https://www.analyticsvidhya.com/contact/>) to learn from the very basics.

General Parameters

These define the overall functionality of XGBoost.

1. booster [default=gbtree]

- Select the type of model to run at each iteration. It has 2 options:
 - gbtree: tree-based models
 - gblinear: linear models

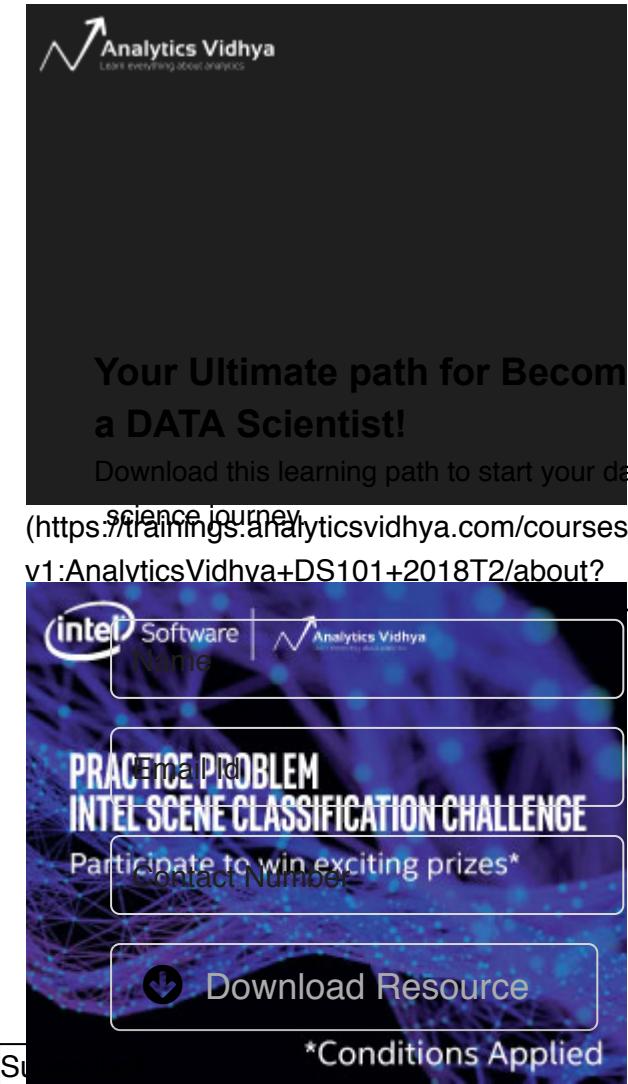

2. silent [default=0]:

- Silent mode is activated if set to 1, i.e. no running messages will be printed.
- It's generally good to keep it 0 as the messages might help in understanding the model.

3. nthread [default to maximum number of threads available if not set]

- This is used for parallel processing and number of cores in the system should be entered
- If you wish to run on all cores, value should not be entered and algorithm will detect automatically

(https://datahack.analyticsvidhya.com/contest/practice-problem-intel-scene-classification-challenge/?utm_source=AVStickyBanner2&utm_medium=display2&uti

There are 2 more parameters which are set automatically by XGBoost
LEARN, **ENGAGE**, **COMPETE**, **GET HIRED**, **COURSES** ✓
and you need not worry about them. Let's move on to Booster parameters.

CONTACT (HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/)

Booster Parameters

Though there are 2 types of boosters, I'll consider only **tree booster** here because it always outperforms the linear booster and thus the later is rarely used.

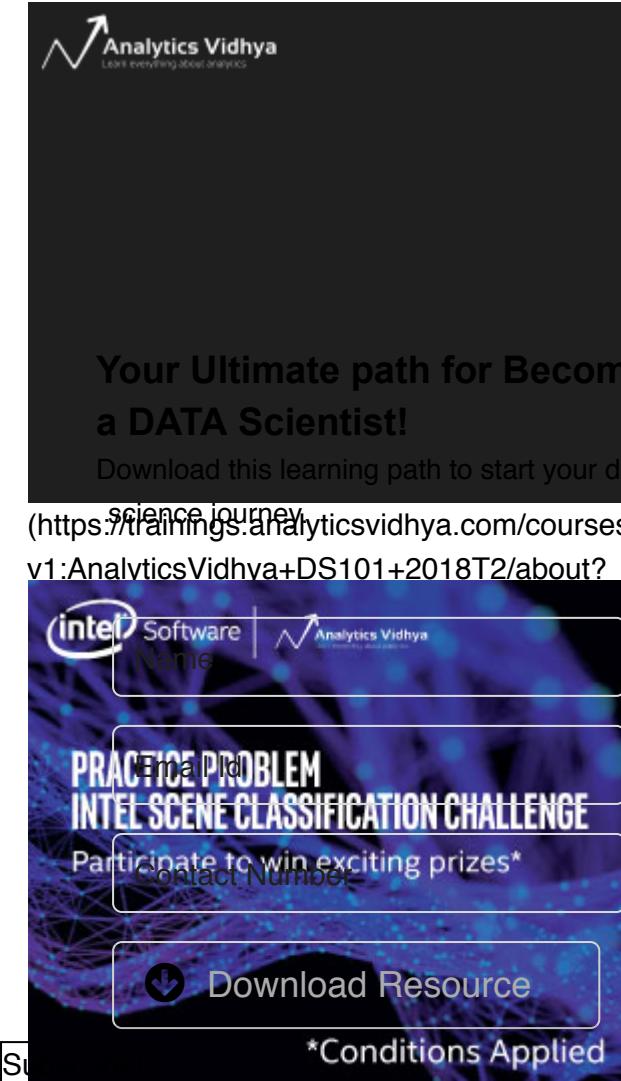

1. **eta [default=0.3]**

- Analogous to learning rate in GBM
- Makes the model more robust by shrinking the weights on each step
- Typical final values to be used: 0.01-0.2

2. **min_child_weight [default=1]**

- Defines the minimum sum of weights of all observations required in a child.
- This is similar to **min_child_leaf** in GBM but not exactly. This refers to min “sum of weights” of observations while GBM has min “number of observations”.
- Used to control over-fitting. Higher values prevent a model from learning relations which might be highly specific to the particular sample selected for a tree.
- Too high values can lead to under-fitting hence, it should be tuned using CV.

(https://datahack.analyticsvidhya.com/contest/practice-problem-intel-scene-classification-challenge/?utm_source=AVStickyBanner2&utm_medium=display2&uti)

3. **max_depth [default=6]**

LEARN ➜ ENGAGE ➜ COMPETE ➜ GET HIRED ➜ COURSES ➜

- The maximum depth of a tree, same as GBM.
CONTACT (<https://www.analyticsvidhya.com/contact/>)
sample.
- Used to control over-fitting as higher depth will allow model to learn relations specific to a particular sample.
- Should be tuned using CV.
- Typical values: 3-10

4. **max_leaf_nodes**

- The maximum number of terminal nodes or leaves in a tree.
- Can be defined in place of max_depth. Since binary trees are created, a depth of 'n' would produce a maximum of 2^n leaves.
- If this is defined, GBM will ignore max_depth.

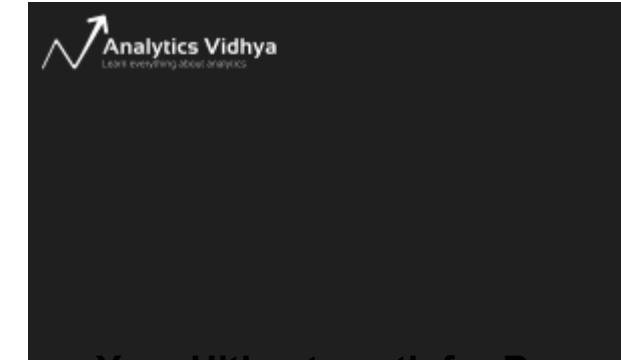

5. **gamma [default=0]**

- A node is split only when the resulting split gives a positive reduction in the loss function. Gamma specifies the minimum loss reduction required to make a split.
- Makes the algorithm conservative. The values can vary depending on the loss function and should be tuned.

6. **max_delta_step [default=0]**

- In maximum delta step we allow each tree's weight estimation to be. If the value is set to 0, it means there is no constraint. If it is set to a positive value, it can help making the update step more conservative.

science journey
(<https://trainings.analyticsvidhya.com/courses/course-v1:AnalyticsVidhya+DS101+2018T2/about?>

A promotional banner for the Intel Scene Classification Challenge. It features the Intel Software logo and the Analytics Vidhya logo. The text "PRACTICE PROBLEM INTEL SCENE CLASSIFICATION CHALLENGE" is prominently displayed. Below it, there are fields for "Email Id" and "Contact Number" with a note "Participate to win exciting prizes*". At the bottom, there is a button labeled "Download Resource" with a download icon. A small note at the bottom right says "*Conditions Applied".

- Usually this parameter is not needed, but it might help in logistic regression when class is extremely imbalanced.
 - This is generally not used but you can explore further if you wish.
- CONTACT** (<https://www.analyticsvidhya.com/contact/>)

7. **subsample [default=1]**

- Same as the subsample of GBM. Denotes the fraction of observations to be randomly samples for each tree.
- Lower values make the algorithm more conservative and prevents overfitting but too small values might lead to under-fitting.
- Typical values: 0.5-1

8. **colsample_bytree [default=1]**

- Similar to max_features in GBM. Denotes the fraction of columns to be randomly samples for each tree.
- Typical values: 0.5-1

9. **colsample_bylevel [default=1]**

- Denotes the subsample ratio of columns for each split, in each level.
- I don't use this often because subsample and colsample_bytree will do the job for you. but you can explore further if you feel so.

10. **lambda [default=1]**

- L2 regularization term on weights (analogous to Ridge regression)

(https://datahack.analyticsvidhya.com/contest/practice-problem-intel-scene-classification-challenge/?utm_source=AVStickyBanner2&utm_medium=display2&uti)

- o This used to handle the regularization part of XGBoost.
- LEARN** ▾ Though many data scientists don't use it often, it should be explored to reduce overfitting.

CONTACT (HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/)

11. **alpha [default=0]**

- o L1 regularization term on weight (analogous to Lasso regression)
- o Can be used in case of very high dimensionality so that the algorithm runs faster when implemented

12. **scale_pos_weight [default=1]**

- o A value greater than 0 should be used in case of high class imbalance as it helps in faster convergence.

Learning Task Parameters

These parameters are used to define the optimization objective the metric to be calculated at each step.

1. **objective [default=reg:linear]**

- o This defines the loss function to be minimized. Mostly used values are:
 - **binary:logistic** –logistic regression for binary classification, returns predicted probability (not class)
 - **multi:softmax** –multiclass classification using the softmax objective, returns predicted class (not probability)

(https://datahack.analyticsvidhya.com/contest/practice-problem-intel-scene-classification-challenge/?utm_source=AVStickyBanner2&utm_medium=display2&uti)

probabilities)
LEARN ▾ **ENGAGE** you COMPETE also Need to GET HIRED COURSES set an additional **num_class** (number of classes)
CONTACT ([HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT](https://www.analyticsvidhya.com/contact))
parameters defining the number of unique classes

- **multi:softprob** – same as softmax, but returns predicted probability of each data point belonging to each class.

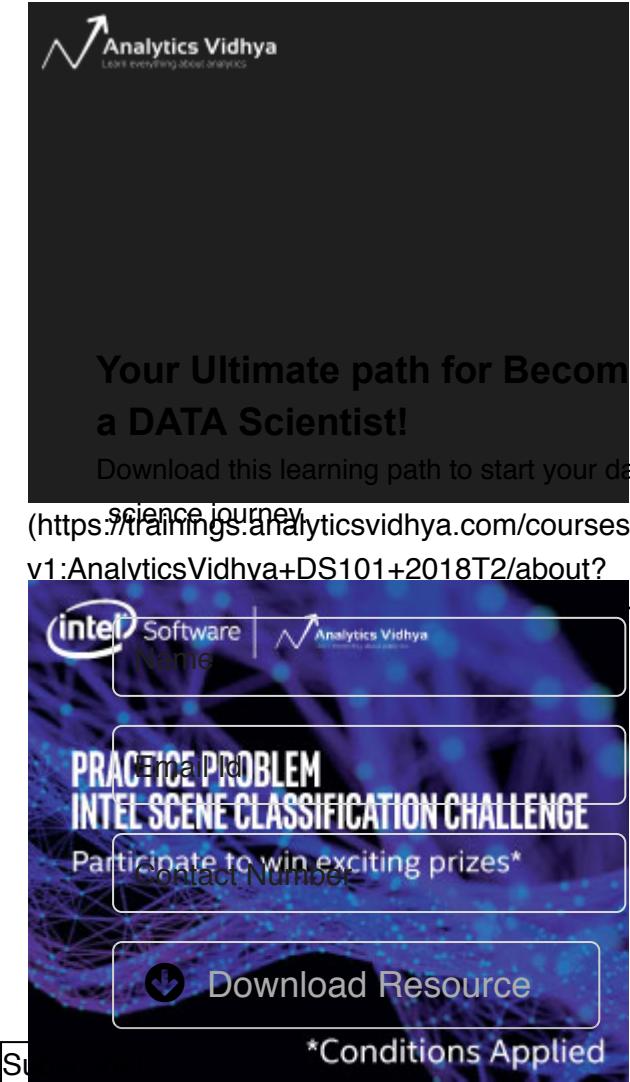

2. eval_metric [default according to objective]

- The metric to be used for validation data.
- The default values are rmse for regression and error for classification.
- Typical values are:
 - **rmse** – root mean square error
 - **mae** – mean absolute error
 - **logloss** – negative log-likelihood
 - **error** – Binary classification error rate (0.5 threshold)
 - **merror** – Multiclass classification error rate
 - **mlogloss** – Multiclass logloss
 - **auc**: Area under the curve

3. seed [default=0]

- The random number seed.
- Can be used for generating reproducible results and also for parameter tuning.

(https://datahack.analyticsvidhya.com/contest/practice-problem-intel-scene-classification-challenge/?utm_source=AVStickyBanner2&utm_medium=display2&uti

If you've been using Scikit-Learn till now, these parameter names might not look familiar. A good news is that `xgboost` module in python has an `sklearn` wrapper called `XGBClassifier`. It uses `sklearn` style naming convention. The parameters names which will change are:

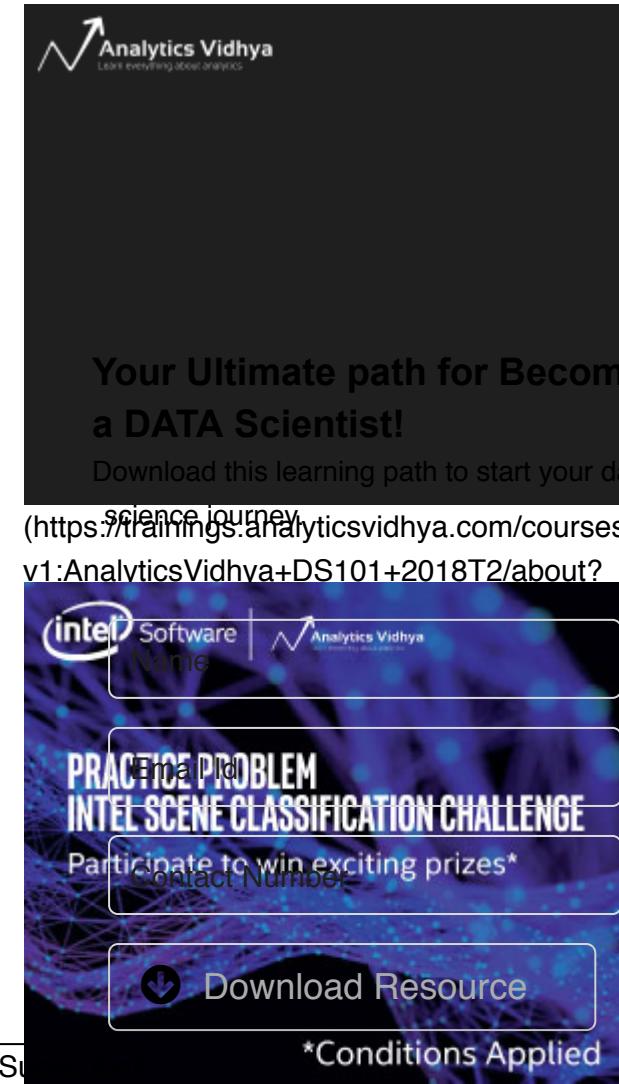

- CONTACT** (<https://www.analyticsvidhya.com/contact/>)
1. eta → learning_rate
 2. lambda → reg_lambda
 3. alpha → reg_alpha

You must be wondering that we have defined everything except something similar to the “n_estimators” parameter in GBM. Well this exists as a parameter in `XGBClassifier`. However, it has to be passed as “num_boosting_rounds” while calling the fit function in the standard `xgboost` implementation.

I recommend you to go through the following parts of `xgboost` guide to better understand the parameters and codes:

1. [XGBoost Parameters \(official guide\)](#)
(<http://xgboost.readthedocs.org/en/latest/parameter.html#general-parameters>).
2. [XGBoost Demo Codes \(xgboost GitHub repository\)](#).
(<https://github.com/dmlc/xgboost/tree/master/demo/guide-python>).
3. [Python API Reference \(official guide\)](#).
(http://xgboost.readthedocs.org/en/latest/python/python_api.html).

(https://datahack.analyticsvidhya.com/contest/practice-problem-intel-scene-classification-challenge/?utm_source=AVStickyBanner2&utm_medium=display2&uti)

3. Parameter Tuning with Example

LEARN ▾ ENGAGE ▾ COMPETE ▾ GET HIRED ▾ COURSES ▾

We will take the data set from Data Hackathon 3.x AV hackathon, [CONTACT US](https://www.analyticsvidhya.com/contact/) that can be found in the GBM article (<https://www.analyticsvidhya.com/blog/2016/02/complete-guide-parameter-tuning-gradient-boosting-gbm-python/>). The details of the problem can be found on the [competition](http://datahack.analyticsvidhya.com/contest/data-hackathon-3x) page (<http://datahack.analyticsvidhya.com/contest/data-hackathon-3x>). You can download the data set from [here](https://www.analyticsvidhya.com/wp-content/uploads/2016/02/Dataset.rar) (<https://www.analyticsvidhya.com/wp-content/uploads/2016/02/Dataset.rar>). I have performed the following steps:

1. City variable dropped because of too many categories
2. DOB converted to Age | DOB dropped
3. EMI_Loan_Submitted_Missing created which is 1 if EMI_Loan_Submitted was missing else 0 | Original variable EMI_Loan_Submitted dropped
4. EmployerName dropped because of too many categories
5. Existing_EMI imputed with 0 (median) since only 111 values were missing
6. Interest_Rate_Missing created which is 1 if Interest_Rate was missing else 0 | Original variable Interest_Rate dropped
7. Lead_Creation_Date dropped because made little intuitive impact on outcome
8. Loan_Amount_Applied, Loan_Tenure_Applied imputed with median values
9. Loan_Amount_Submitted_Missing created which is 1 if Loan_Amount_Submitted was missing else 0 | Original variable

This code is slightly different from what I used for GBM. The focus of this article is to cover the concepts and not coding. Please feel free to drop a note in the comments if you find any challenges in understanding any part of it. Note that xgboost's sklearn wrapper doesn't have a "feature_importances" metric but a get_fscore() function which does the same job.

General Approach for Parameter Tuning

We will use an approach similar to that of GBM here. The various steps to be performed are:

1. Choose a relatively **high learning rate**. Generally a learning rate of 0.1 works but somewhere between 0.05 to 0.3 should

^

work for different problems. Determine the **optimum number of trees for this learning rate**. XGBoost has a very useful function called as “cv” which performs cross-validation at each boosting iteration and thus return the optimum number of trees required.

CONTACT <https://www.analyticsvidhya.com/contact>

2. **Tune tree-specific parameters** (max_depth, min_child_weight, gamma, subsample, colsample_bytree) for decided learning rate and number of trees. Note that we can choose different parameters to define a tree and I'll take up an example here.
3. **Tune regularization parameters** (lambda, alpha) for xgboost which can help reduce model complexity and enhance performance.
4. **Lower the learning rate** and decide the optimal parameters .

Let us look at a more detailed step by step approach.

Step 1: Fix learning rate and number of estimators for tuning tree-based parameters

In order to decide on boosting parameters, we need to set some initial values of other parameters. Lets take the following values:

1. **max_depth = 5** : This should be between 3-10. I've started with 5 but you can choose a different number as well. 4-6 can be good starting points.
2. **min_child_weight = 1** : A smaller value is chosen because it is a highly imbalanced class problem and leaf nodes can have smaller size groups.

3. **gamma = 0** : A smaller value like 0.1-0.2 can also be chosen for LEARN ENGAGE COMPETE GET HIRED COURSES starting. This will anyways be tuned later.
4. **subsample, colsample_bytree = 0.8** : This is a commonly used used start value. Typical values range between 0.5-0.9
[CONTACT US](https://www.analyticsvidhya.com/contact/)
5. **scale_pos_weight = 1**: Because of high class imbalance.

Please note that all the above are just initial estimates and will be tuned later. Lets take the default learning rate of 0.1 here and check the optimum number of trees using cv function of xgboost. The function defined above will do it for us.

Note: You will see the test AUC as "AUC Score (Test)" in the outputs here. But this would not appear if you try to run the command on your system as the data is not made public. It's provided here just for reference. The part of the code which generates this output has been removed here.

Step 2: Tune max_depth and min_child_weight

We tune these first as they will have the highest impact on model outcome. To start with, let's set wider ranges and then we will perform another iteration for smaller ranges.

Important Note: I'll be doing some heavy-duty grid searched in this section which can take 15-30 mins or even more time to run depending on your system. You can vary the number of values you are testing based on what your system can handle.

A banner for the "Introducing Intel Software Analytics Vidhya Data Science Learning Path". It features the Intel logo and the Analytics Vidhya logo. The text on the banner includes "PRACTICE PROBLEM", "INTEL SCENE CLASSIFICATION CHALLENGE", "Participate to win exciting prizes*", "Contact Number", "Download Resource", and "Conditions Applied". There is also a small "Skip" button at the bottom left.

Here, we get the optimum values as **4** for **max_depth** and **6** for **min_child_weight**. Also, we can see the CV score increasing slightly. Note that as the model performance increases, it becomes exponentially difficult to achieve even marginal improvements in performance.

CONTACT US <https://www.analyticsvidhya.com/contact>

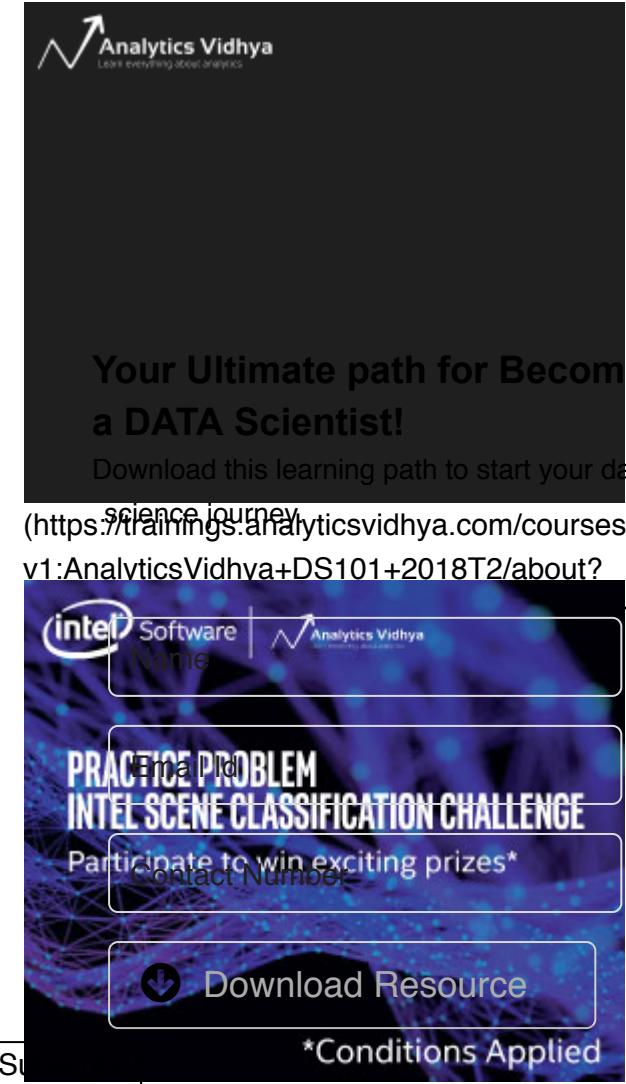

You would have noticed that here we got 6 as optimum value for min_child_weight but we haven't tried values more than 6. We can do that as follow::

```
param_test2b = {
    'min_child_weight':[6,8,10,12]
}

gsearch2b = GridSearchCV(estimator = XGBClassifier( learning_rate=0.1, n_estimators=140, max_depth=4,
    min_child_weight=2, gamma=0, subsample=0.8, colsample_bytree=0.8,
    objective= 'binary:logistic', nthread=4, scale_pos_weight=1,seed=27),
    param_grid = param_test2b, scoring='roc_auc',n_jobs=4,verbose=False, cv=5)
gsearch2b.fit(train[predictors],train[target])
```

```
modelfit(gsearch3.best_estimator_, train, predictors)
gsearch2b.grid_scores_, gsearch2b.best_params_, gsearch2b.best_score_
```

(https://datahack.analyticsvidhya.com/contest/practice-problem-intel-scene-classification-challenge/?utm_source=AVStickyBanner2&utm_medium=display2&uti

Step 5: Tuning Regularization Parameters

Next step is to apply regularization to reduce overfitting. Though many people don't use this parameters much as gamma provides a substantial way of controlling complexity. But we should always try it. I'll tune 'reg_alpha' value here and leave it upto you to try different values of 'reg_lambda'.

We can see that the CV score is less than the previous case. But the values tried are very widespread, we should try values closer to the optimum here (0.01) to see if we get something better.

CONTACT ([HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/](https://www.analyticsvidhya.com/contact/))

```
param_test7 = {

Again we can see slight improvement in the score.

Step 6: Reducing Learning Rate

Lastly, we should lower the learning rate and add more trees. Lets use the cv function of XGBoost to do the job again.

Now we can see a significant boost in performance and the effect of parameter tuning is clearer.

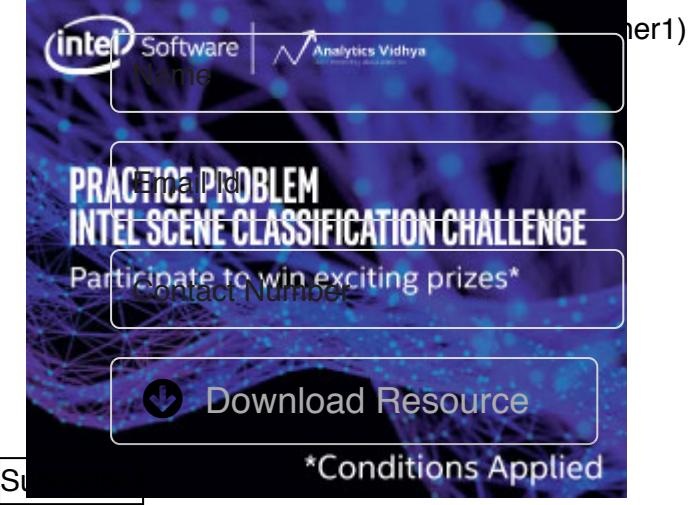

As we come to the end, I would like to share 2 key thoughts:

1. It is **difficult to get a very big leap** in performance by just using **parameter tuning** or **slightly better models**. The max score for GBM was 0.8487 while XGBoost gave 0.8494. This is a decent improvement but not something very substantial.

(https://datahack.analyticsvidhya.com/contest/practice-problem-intel-scene-classification-challenge/?utm_source=AVStickyBanner2&utm_medium=display2&uti

(<https://trainings.analyticsvidhya.com/courses/course-v1:AnalyticsVidhya+DS101+2018T2/about?>)

2. A significant jump can be obtained by other methods like **feature engineering**, creating **ensemble** of models, **stacking**, etc

You can also download the iPython notebook with all these model codes from my [GitHub account](#)

(https://github.com/aarshayj/Analytics_Vidhya/tree/master/Articles/Parameter)

For codes in R, you can refer to [this article](#)

(<https://www.analyticsvidhya.com/blog/2016/01/xgboost-algorithm-easy-steps/>).

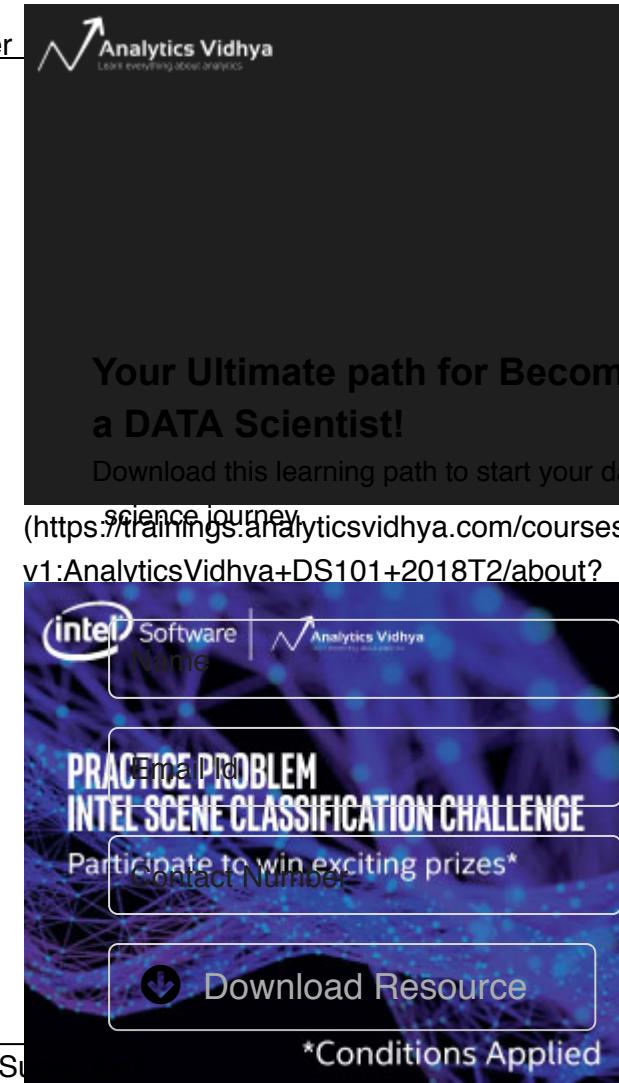

End Notes

This article was based on developing a XGBoost model end-to-end. We started with discussing **why XGBoost has superior performance over GBM** which was followed by detailed discussion on the **various parameters** involved. We also defined a generic function which you can re-use for making models.

Finally, we discussed the **general approach** towards tackling a problem with XGBoost and also worked out the **AV Data Hackathon 3.x problem** through that approach.

I hope you found this useful and now you feel more confident to apply XGBoost in solving a data science problem. You can try this out in our upcoming hackathons.

(https://datahack.analyticsvidhya.com/contest/practice-problem-intel-scene-classification-challenge/?utm_source=AVStickyBanner2&utm_medium=display2&uti)

Did you like this article? Would you like to share some other hacks which you implement while making XGBoost models? Please feel free to drop a note in the comments below and I'll be glad to discuss.

CONTACT (<https://www.analyticsvidhya.com/contact/>)

Hi guys,

Thanks for reaching out!

I've given a link to an article

(<http://www.analyticsvidhya.com/blog/2016/01/xgboost-algorithm-easy-steps/>) (<http://www.analyticsvidhya.com/blog/2016/01/xgboost-algorithm-easy-steps/>) in my above article. This has some R codes for implementing XGBoost in R.

This won't replicate the results I found here but will definitely help you. Also, I don't use R much but think it should not be very difficult for someone to code it in R. I encourage you to give it a try and share the code as well if you wish :D.

In the meanwhile, I'll also try to get someone to write R codes. I'll get back to you if I find something.

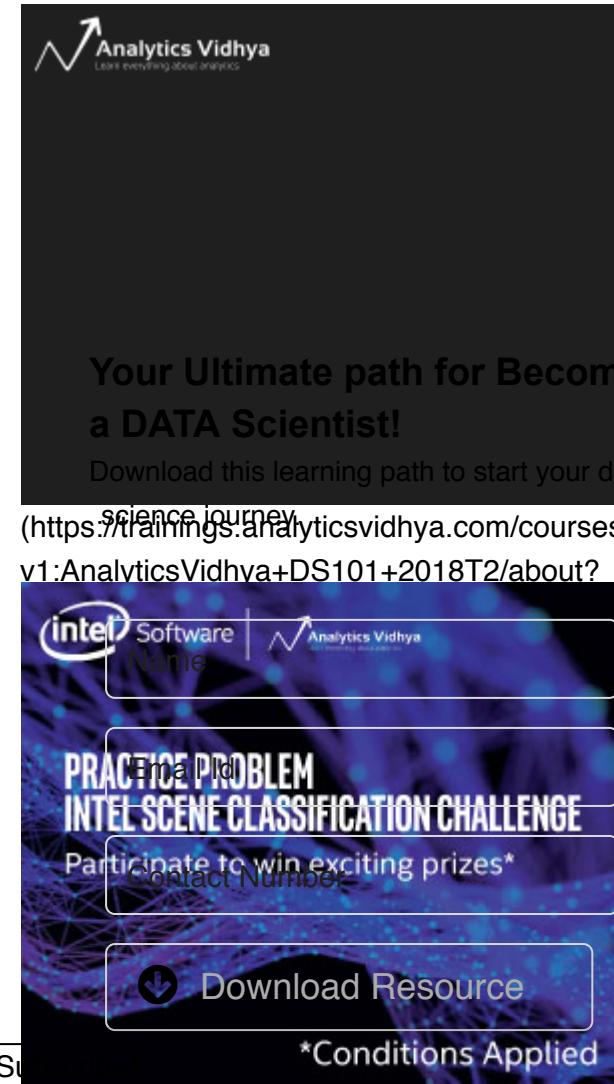

Cheers,
Aarshay

CONTACT (HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/)
I am wondering whether in practice it is useful such an extreme tuning of the parameters ... it seems that often the standard deviation on the cross validation folds does not allow to really distinguish between different parameters sets... any thoughts on that?

AARSHAY JAIN

March 2, 2016 at 8:09 am

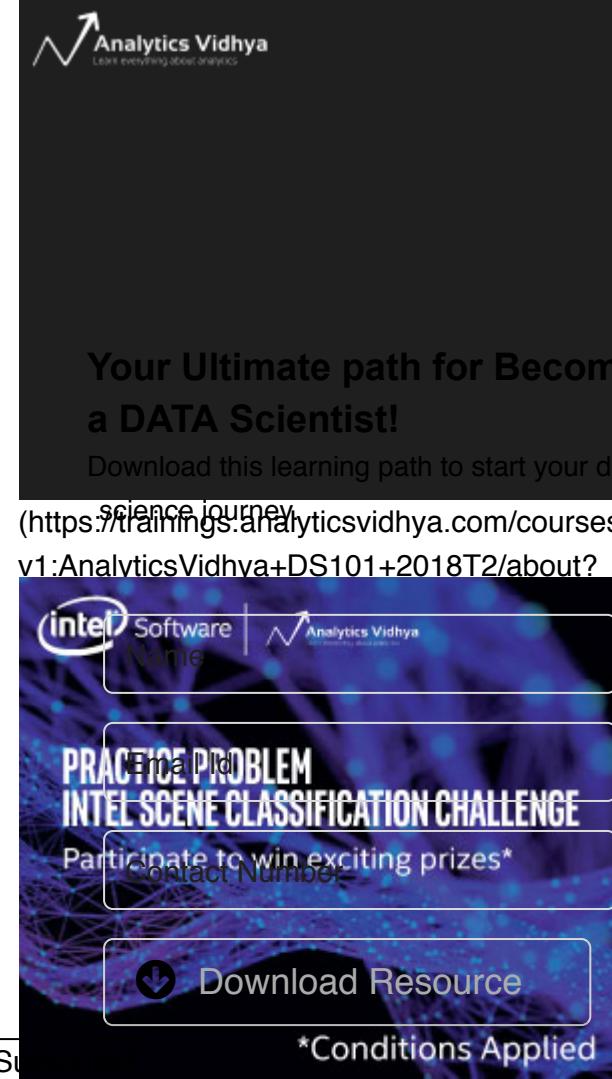

[Reply](#)

(<https://www.analyticsvidhya.com/blog/2016/03/complete-guide-parameter-tuning-xgboost-with-codes-python/#comment-106472>).

Agree but partially. Some thoughts:

1. Though the standard deviations are high, as the mean comes down, their individual values should also come down (though theoretically not necessary). Actually the point is that some basic tuning helps but as we go deeper, the gains are just marginal. If you think practically, the gains might not be significant. But when you are in a competition, these can have an impact because people are close and many times the difference between winning and losing is 0.001 or even smaller.

(https://datahack.analyticsvidhya.com/contest/practice-problem-intel-scene-classification-challenge/?utm_source=AVStickyBanner2&utm_medium=display2&uti)

The image shows a dark-themed landing page for a data science challenge. At the top left is the Analytics Vidhya logo with the tagline "Learn everything about analytics". On the right is a close button (an 'X'). Below the logo, the main title reads "Your Ultimate path for Becoming a DATA Scientist!". Underneath, it says "Download this learning path to start your data science journey" and provides a link: (<https://trainings.analyticsvidhya.com/courses/course-v1:AnalyticsVidhya+DS101+2018T2/about?>). The background features a blue and purple abstract design. In the center, there's a section for the "PRACTICE PROBLEM INTEL SCENE CLASSIFICATION CHALLENGE". It includes fields for "Email Id" and "Contact Number", both with placeholder text "Enter Email Id" and "Enter Contact Number". Below these is a large blue button with the text "Download Resource". At the bottom right, it says "*Conditions Applied".

LEARN ↘ the **ENGAGE**, **COMPETE**, **GET HIRED**, **COURSES** ↗ the CV increases just marginally, the impact on test set may be higher. I've seen Kaggle master's taking AWS instances for hyper parameter tuning to take care of small differences in values.

2. As we tune our models, it becomes more robust. Even if the CV increases just marginally, the impact on test set may be higher. I've seen Kaggle master's taking AWS instances for hyper parameter tuning to take care of small differences in values.
3. I actually look at both mean and std of CV. There are instances where the mean is almost the same but std is lower. You can prefer those models at times.
4. As I mentioned in the end, techniques like feature engineering and blending have a much greater impact than parameter tuning. For instance, I generally do some parameter tuning and then run 10 different models on same parameters but different seeds. Averaging their results generally gives a good boost to the performance of the model.

Hope this helps. Please share your thoughts.

Hi, first of all thank you for writing the article (I forgot to thank you for that in my previous post :-)).

CONTACT ([HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/](https://www.analyticsvidhya.com/contact/))

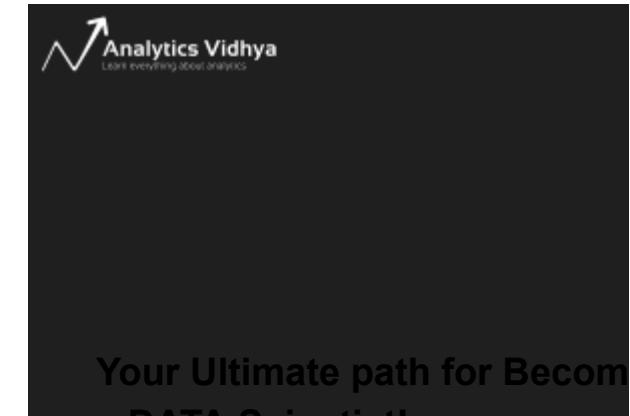

Regarding your points a few more thoughts:

1.-2. My gut feeling is that if the uncertainty on the mean is high (and usually it is proportional to the std) an apparent small average improvement maybe be actually due to stochastic effects (choice of a particular training set): hence would probably in general, not transfer to an independent test set. I wouldn't know how to make this argument more precise though.

3. That is probably useful indeed: another common choice is to choose the parameter set which provides the model of lowest complexity within one or half std from the minimum.

4. Yes, if the learning of these models is done by solving a non-convex optimization problem, that blending will in general help (indeed you have a chance of effectively averaging different models). It should work even better if you blend intrinsically different models (like linear + other types of nonlinear classifiers) since then you are even more sure that the decision boundaries are not correlated.

Thanks a lot for sharing your feedback.

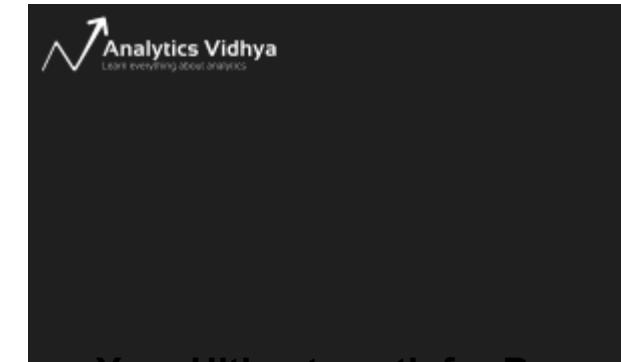

1-2: I'm getting your point. I think you are right. Very small improvements might actually be due to randomness. Probably we should consider model tuning in the end and use some moderate models to test out feature engineering.

3. Valid point. But how do we judge complexity in case of models like GBM or XGBoost? Is it related to training accuracy?

4. Agree totally.

Thanks for your comments. There is still so much for me to learn and what's better than interacting with

Luca if you want to make more precise what you are saying the following is the way. Suppose you want to check the null hypothesis that two groups have different spending habits given their sample means and sample variances. How would you go about it. One method is ANOVA and another is to realise that under the assumption that each is normally distributed, the difference is also normally distributed with variance $\text{std}_A \sqrt{n_A} + \text{std}_B \sqrt{n_B}$ and asking for the p-value of the observed difference in sample means.

This is the same problem. You have two difference means and you want to ask if the difference is statistically significant. Given that you are using 5-fold CV the square-root factors are about 2 so the roughly the standard deviation of the difference in sample means is about the standard deviation you observe and you can see that if the difference in sample means is within one-sigma it is 65% likely to be ‘statistical fluctuation’ as you put it (correctly).

If you want to be more rigorous using t-distributions as n=5 either you can do that but as a ball park estimate I would say that in this problem is standard deviation is comparable to mean, an improvement much smaller than the mean means nothing (technically said, it does not rule out the null hypothesis that the parameter tuning did not buy you anything.)

Hi..

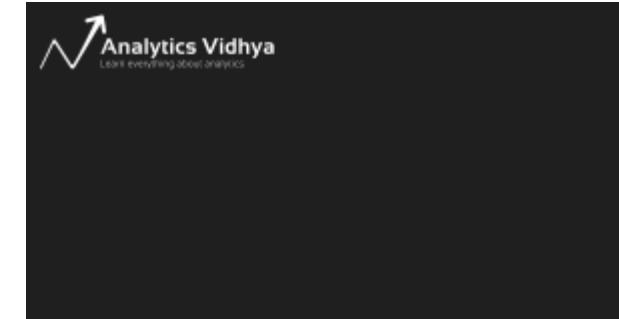

Nice article with lots of informations.

I was wondering if I can clear my understandings on following :

a) On Handling Missing Values, XGBoost tries different things as it encounters a missing value on each node and learns which path to take for missing values in future.

Please elaborate on this.

Glad you liked it.. My responses below:

- a) When xgboost encounters a missing value at a node, it tries both left and right hand split and learns the way leading to higher loss for each node. It then does the same when working on testing data.
- b) Yes it is available in sklearn wrapper of xgboost package. It will pass the parameters in actual xgboost format (not sklearn wrapper). The cv function requires parameters in that format itself.

During feature engineering, if I want to check if a simple change is producing any effect on performance, should I go through the entire process of fine tuning the parameters, which is obviously better than keeping the same parameter values but takes lot of time. So, how often do you tune your parameters?

I don't think that should be required. Once you tune your model on a baseline input, it should be good enough to check if the features are working.

CONTACT ([HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/](https://www.analyticsvidhya.com/contact/))

If you're experimenting a lot, it might be a good idea to use random forest to check if feature improved the accuracy. RF models run faster and are not much affected by tuning.

Hope this helps.

Hi Jain thanks for you effort, this guide is simply awesome !

But just because I wasn't able to find the modified Train Data from the repository (in effect I wasn't able to find the repository, my fault for sure, but I'm working on it), I had to rebuild the modified train data (good exercise !) and I want to share with everyone my code:

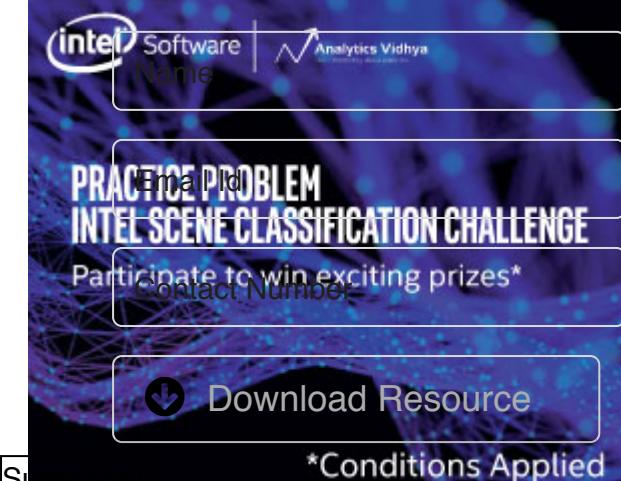

```
train.ix[ train['DOB'].isnull(), 'DOB' ] = train['DOB'].max()
train['Age'] = (pd.to_datetime( train['DOB'].max(), dayfirst=True ) - 
pd.to_datetime( train['DOB'], dayfirst=True )).astype('int64')
train.ix[ train['EMI_Loan_Submitted'].isnull(),
'EMI_Loan_Submitted_Missing' ] = 1
train.ix[ train['EMI_Loan_Submitted'].notnull(),
'EMI_Loan_Submitted_Missing' ] = 0
train.ix[ train['Existing_EMI'].isnull(), 'Existing_EMI' ] =
train['Existing_EMI'].median()
train.ix[ train['Interest_Rate'].isnull(), 'Interest_Rate_Missing' ] = 1
train.ix[ train['Interest_Rate'].notnull(), 'Interest_Rate_Missing' ] = 0
train.ix[ train['Loan_Amount_Applied'].isnull(), 'Loan_Amount_Applied' ] =
train['Loan_Amount_Applied'].median()
```

(<https://www.analyticsvidhya.com/blog/2016/03/complete-guide-parameter-tuning-xgboost-with-codes-python/#comment-107268>)

I have the error

```
cvresult = xgb.cv(xgb_param, xgtrain,  
num_boost_round=alg.get_params()['n_estimators'], nfold=cv_folds,  
metrics='auc', early_stopping_rounds=early_stopping_rounds,  
show_progress=False)
```

```
raise ValueError('Check your params.\nValueError: Check your params.Early stopping works with single eval metric only.
```

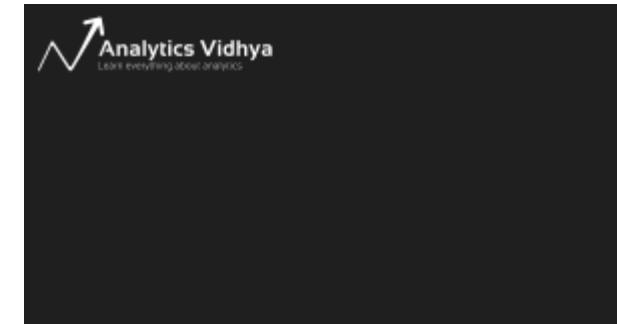

How can I fix it? Thank you in advance.

CONTACT ([HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/](https://www.analyticsvidhya.com/contact/))

What I can understand from the error is that multiple metrics have been defined. But here it's just 'auc'. Please check your xgb_param value. Is it setting a different value for metric?

If problem persists for long, I suggest you start a discussion thread with code and error snapshot. It'll be easier to debug.

Hi Aarshay,

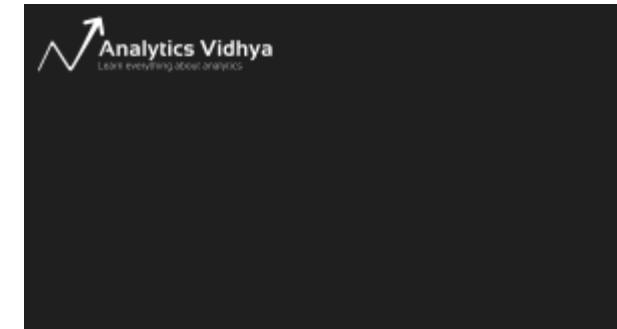

quick question: if I try to do multi-class classification, python send error as follows:

xgb1 = XGBClassifier(

```
learning_rate =0.1,  
n_estimators=1000,  
max_depth=5,  
min_child_weight=1,  
gamma=0,  
subsample=0.8,  
colsample_bytree=0.8,
```

```
n_class=4,  
objective="multi:softmax",  
nthread=4,
```

Hi Daniel,

I don't think the 'n_classes' or any other variant of argument is needed in the sklearn wrapper. It works for me without this argument. Please try removing it.

Hi Aarshay!

Thanks for your prompt response. Yes, you are right I can train without the argument 'n_classes'. However, when I want to use xgb.cv(...) it gives an error:

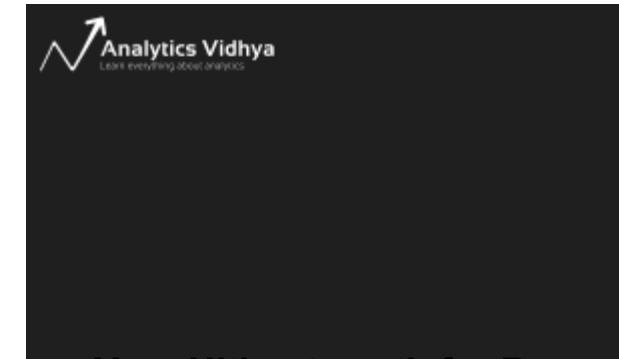

"XGBoostError: must set num_class to use softmax" (the log is below).

So I guess my question is if one can use xgb.cv() for parameter tuning with multi-class classification.

Thanks again in advance!

```
cvresult = xgb.cv(xgb_param, dtrain,
num_boost_round=xgb1.get_params()
['n_estimators'], nfold=5,
early_stopping_rounds=50,
show_progress=False)
```

Hi Daniel,

Yes it can be used. You have to add the parameter ‘num_class’ to the xgb_param dictionary. Use something like this before calling xgb.cv:

xgb_param['num_class'] = k #k = number of classes.

It should work. I use xgb.cv for multi-class problems a lot!

Hi Shan,

As per instructions given in the link that I mentioned above,

I first installed MINGW-64 from the below website

<http://sourceforge.net/project/w64/>

<http://sourceforge.net/project/w64/>.

then I installed cygwin from the below link

https://cygwin.com/setup-x86_64.exe

https://cygwin.com/setup-x86_64.exe.

Hope this helps.

Hi Aarshay,

As always, a great article.

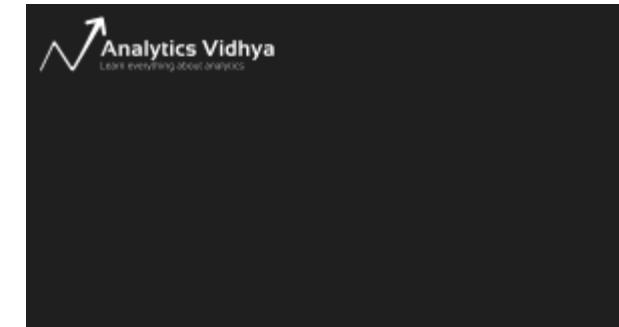

I have two doubts

1. n_estimators=cvresult.shape[0] we have set this while fitting the algorithm for XGBoost. Any specific reason why we did in that way.
2. In the model fit function, we are not generating CV score as the output.. How are we automatically able to get it in box with red background. I am not getting CV value. Am I missing something?

Can you please clarify

Regards,
Praveen

Hi..Praveen Gupta Sanka,

Can you please share how to install xgboost in python/anaconda env. ? r

I followed instructions from the below link and it worked for me

<http://stackoverflow.com/a/35119904>
(<http://stackoverflow.com/a/35119904>).

Can you please share how you installed “mingw64” and “Cygwin shell” on laptop ? Need hand holding on the same.

Thanks in advance,

AARSHAY JAIN

LEARN I've used xgb.cv here for determining the optimum number of estimators for a given learning rate. After running xgb.cv, this statement overwrites the default number of estimators to that obtained from xgb.cv. The variable cvresults is a dataframe with as many rows as the number of final estimators.

2. The red box is also a result of the xgb.cv function call.

When I try the GridSearchCV my system does not do anything. It sits there for a long time, but I can check the activity monitor and nothing happens, no crash, no message, no activity. Any clue?

This is strange indeed. Right off the bat, I think of following diagnosis:

1. Run the GridSearchCV for a very small sample of data,

I am sorry I am not clear. In step 1 you use a function, modelfit. This function will output something like "stopping. Best iteration [n]". In your case that number is 140. I am not sure I understand how you use this information, is this used with the n_estimators parameters?

Sorry to bother you again, but would you mind elaborating a little more on the code in modelfit, in particular:

if useTrainCV:

```
xgb_param = alg.get_xgb_params()  
xgtrain = xgb.DMatrix(dtrain[predictors].values,  
label=dtrain[target].values)  
cvresult = xgb.cv(xgb_param, xgtrain,  
num_boost_round=alg.get_params()['n_estimators'], nfold=cv_folds,  
metrics='auc', early_stopping_rounds=early_stopping_rounds,  
show_progress=False)  
alg.set_params(n_estimators=cvresult.shape[0])
```

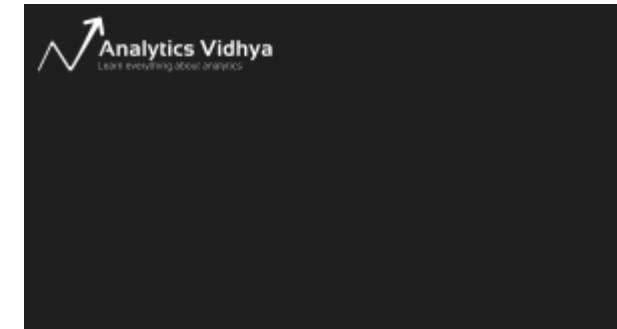

Thank you very for your time.

CONTACT ([HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/](https://www.analyticsvidhya.com/contact/))

sure. this part of the code would check the optimal number of estimators using the “cv” function of xgboost. This works only if the useTrainCV argument of the function is set as True. If True, this will run “xgb.cv”, determine the optimal value for n_estimators and replace the value set by the user with this value. While using this case, you should remember to set a very high value for n_estimators, i.e. higher than the expected optimal value range. Hope this makes sense.

CONTACT ([HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/](https://www.analyticsvidhya.com/contact/))

As mentioned above, there are 2 ways to use xgboost:

1. sklearn wrapper – allows pandas dataframe as input

2. raw xgboost functions – requires a DMatrix format provided by xgboost.

So this is just a necessary pre-processing step if you are not using sklearn wrapper.

Similarly,, get_xgb_params() return the parameters in the format required by the raw xgboost functions.

All this is needed because xgboost.cv has not been implemented in the sklearn wrapper and we have to use the original functions for that.

Nice article @Aarshay
[CONTACT \(HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/\)](https://www.analyticsvidhya.com/contact/)
One question on setting the parameters for xgb here.
Can the value of n_estimators be only set or we can derive different parameters like max_depth, seed, etc??

If we can derive all the parameters then how is this different from GridSearchCV?

AARSHAY JAIN [Reply](#)

I am sorry i should have been more clear with the question.

My question was more conceptual in nature. In the modelfit() method you have show that setting the value of estimators using the n_estimators=cvresult.shape is possible, but there are more parameters to the xgb classifier eg. max_depth, seed, colsample_bytree, nthread etc.

Is it possible to find out optimal values of these parameters also via cv method.

I surely know that this can be done by GridSearchCV, just wondering if at all its possible by the sklearn wrapper cv() method?

Thanks for the help.

Hello,

really great article, I have learnt a lot from it.

One question, you mention the default value for scale_pos_weight is 0. Where have you got this information from? Checking the source code (regression_obj.cc) I have found the value to be 1 by default, with a lower bound of 0. In the R version, that I use, the parameter does not appear explicitly.

Can you please clarify?

According to this: <https://www.kaggle.com/c/santander-customer-satisfaction/forums/t/20662/overtuning-hyper-parameters-especially-re-xgboost> (<https://www.kaggle.com/c/santander-customer-satisfaction/forums/t/20662/overtuning-hyper-parameters-especially-re-xgboost>)

If you are using logistic trees, as I understand your article describes, alpha and lambda don't play any role.

I would appreciate your feedback

Thanks in advance

Hi Jose,
LEARN ▾ **ENGAGE** ▾ **COMPETE** ▾ **GET HIRED** ▾ **COURSES** ▾

I'm not sure which part of the post you are referring to. If it is the part which says "reg_alpha, reg_lambda are not used in CONTACT (<https://www.analyticsvidhya.com/contact>) tree booster", then this is right.

But the parameters which I've mentioned are alpha and lambda and not reg_alpha and reg_lambda. Regularization is used in tree-booster as well where the constraint is put on the score of each leaf in the tree.

Please let me know if its still unclear.

Cheers!

JOSE MAGANA

(<https://www.analyticsvidhya.com/blog/2016/03/c-guide-parameter-tuning-xgboost-with-codes-python/#comment-110796>).

If you check the source code, you would observe that alpha is nothing but an alias for reg_alpha. Files> param.h and gblinear.cc.
In section 2 of your article you mention a similar mapping of names for the case of Python.
Can you tell me where in the code is alpha used in the case of trees? What is the effect?

I guess the nomenclature varies in different implementations. If you read the Tree Boosting part here – <http://xgboost.readthedocs.io/en/latest/> (<http://xgboost.readthedocs.io/en/latest/>) you'll understand how regularization is used for tree boosters. I haven't gone into the coding yet. I was trusting that these guys implement what they say. I don't have time to look into it now but will do sometime later.

Regarding the other point, I agree with you partially. Typically we should use the same folds and see if there is

improvement in most of the folds
(atleast 3 out of 5). I just used mean

here for simplicity and because mostly

it works out. The standard deviation

CONTACT ([HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT](https://www.analyticsvidhya.com/contact))

being similar, a higher mean generally means an improvement in most folds.

It'll be a rare case where 1 fold increases drastically and other decreases. But I agree we should check those things. I didn't want this to become too overwhelming for beginners so decided to stick with the mean.

It is a great blog. It will be better, if you can give a parameter tuning for a regression problem, although a lot of stuff will be similiar to the classification problem.

Hello Aarshay

This is really great article, I have learnt a lot from it.

One question, when i tuning the model using dataset (size = 1gb), the model ran very slowly , do you know why it ran too slowly ?

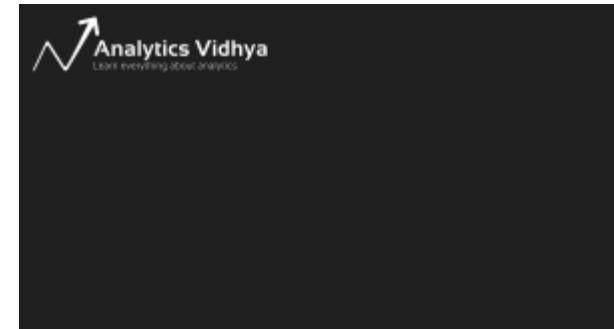

Thanks
